# The lattice parameters and interplanar spacings of some artificially prepared melitites. 

By K. W. Andrews, B.Sc., D.Phil.<br>Research and Development Department, The United Steel Companies<br>Limited, Stocksbridge, near Sheffield.

[Communicated by Dr. F. A. Bannister; read June 24, 1948.]

Introduction.-A laboratory investigation in connexion with some blast-furnace slags, led to the preparation of the five synthetic melilites for which X-ray data are provided. The five compounds represent gehlenite, åkermanite, and three members of the intermediate series of solid solutions, corresponding to 25,50 , and $75 \%$ of åkermanite.

The binary system gehlenite-åkermanite was studied by Ferguson and Buddington, ${ }^{1}$ who established relationships between refractive indices, density, and composition and determined solidus and liquidus curves. The crystal structure of the melilite group of compounds was investigated by Warren, ${ }^{2,3}$ who showed that the structure was based on a tetragonal lattice. In åkermanite the magnesium atoms occupy the centres and corners of the (001) faces, whilst the silicon atoms are at the centres of silicon-oxygen tetrahedra joined together in pairs by a common oxygen atom, thus forming $\mathrm{Si}_{2} \mathrm{O}_{7}$ groups. In going from akermanite to gehlenite magnesium atoms are replaced by aluminium and some of the silicons by aluminium also. The composition of gehlenite is reached when all the magnesium atoms and half the silicon have been replaced in this manner. The replacement may be represented by $\mathrm{Mg}^{2+}+\mathrm{Si}^{4+} \rightleftharpoons \mathrm{Al}^{3+}+\mathrm{Al}^{3+}$. We are not here concerned with the similar replacement of $\mathrm{Ca}+\mathrm{Mg}$ by $\mathrm{Na}+\mathrm{Al}$, which would account for the presence of the sodium atoms usually included in the general formula for melilite.

Experimental Work.-The samples were prepared from pure component oxides of 'analytical reagent' or similar quality. The calcium oxide was prepared by calcining calcium carbonate at a temperature of

[^0]about $950^{\circ} \mathrm{C}$., but all oxides were heated at this temperature immediately before weighing out the quantities required. Samples of a total weight of approximately one gram each were prepared. A technique of careful and prolonged mixing and grinding together was followed, and the mixtures then rammed into cylindrical pellets, ready for firing.

* The values in $\AA$. are obtained by multiplying the kX values by a factor of $\mathrm{I} \cdot 00202$.

The compositions of the samples are listed in table I. It is considered that the probable errors in composition arising from the method of preparation employed are less than would be obtained by ordinary chemical analysis of much larger samples. Samples of the size prepared are small enough to be thoroughly mixed by careful hand-mixing, but large enough for the components to be sufficiently accurately weighed, and for the effect of small losses (in any case practically nil) to be negligible in proportion.

The heating schedule was: The samples were heated from 20 to $1300^{\circ} \mathrm{C}$. in approximately 4 hours, and then held at $1300^{\circ} \mathrm{C}$. for approximately 3 hours, and finally cooled down with the furnace.

The samples were examined by the $X$-ray powder method in the 9 cm . diameter camera and the photographs which were taken with $\mathrm{Co}-\mathrm{K} \alpha$ radiation are illustrated in fig. 1. The photographs showed that the crystals were reasonably well developed, and sharp lines were generally

| Åkermanite | $\ldots$ | $\ldots$ | 0 | 25 | 50 | 75 | 100 |

obtained up to high angles. The sample representing $50 \%$ gehlenite, and $50 \%$ åkermanite in mutual solid solution (no. 3), however, showed somewhat poorer lines at high angles than the others. No change was observed after prolonged periods of heating with this or the other samples, and the photographs provided the accuracy desired.

The values of the lattice parameters and axial ratios corresponding to the five synthetic samples are included with the composition data in table I. The results are plotted against composition in fig. 2 , which shows how, proceeding from gehlenite to åkermanite, the replacement of 2 Al by $\mathrm{Mg}+\mathrm{Si}$ leads to an increase in the $a$ spacing and a decrease in the $c$ spacing, with a corresponding decrease in axial ratio.

Measurements were made in kX units and converted to Ångström units as indicated in table I. The $a$ and $c$ parameters were then used to calculate interplanar spacings which are recorded in table II, together

* Lines whose relative positions are reversed by axial ratio change.
with the corresponding indices and relative intensities. These calculated interplanar spacings are expected to be useful for the identification of members of this series of solid solutions. The actual calculated values are retained (rather than a mean value) where two lines are too close together to be resolved. It will thus be observed how some pairs of lines
such as 102 and 221 , or 312 and 411, approach, coincide, and theu separate on the opposite side of each other, as the axial ratio changes

Fig. 2. Lattice spacing relationships in the gehlenite-åkermanite series.
from one end of the series to the other. Lines which as a result are displaced in the otherwise strict order of decreasing magnitude of $d_{b k l}$ in the table, are therefore indicated by an asterisk.

Conclusions.-The five members of the solid solution series examined have been sufficient to indicate to a reasonable degree of accuracy the
lattice parameter variations accompanying the isomorphous substitution represented by $\mathrm{Mg}+\mathrm{Si} \rightleftharpoons \mathrm{Al}+\mathrm{Al}$. The ionic radii are in the order Mg $>\mathrm{Al}>\mathrm{Si}$, and commencing with åkermanite the replacement of Mg by Al would be expected to lead to a contraction of the lattice, whilst the replacement of some of the Si atoms by Al would result in an increase in the dimensions of the silicon-oxygen tetrahedra linked in pairs. The combination of these two tendencies leads to the resultant decrease of the $a$ parameter and increase of the $c$ parameter proceeding from åkermanite to gehlenite (i.e. from right to left in fig. 2).

Interplanar spacing data are provided, and are expected to be of use for the identification of members of this series of solid solutions, providing that isomorphous substitution of ions other than those considered is not large enough to affect the spacings seriously. The presence of sodium ions in melilites has been referred to in the introduction. The replacement of magnesium by divalent iron (and possibly also by manganese) and of aluminium by trivalent iron is expected. In the mineral hardystonite $\mathrm{Ca}_{2} \mathrm{ZnSi}_{2} \mathrm{O}_{7}$ the Mg of åkermanite is completely replaced by zinc. The possibility of other substitutions is not excluded providing the ionic radii are of a similar order to the radii of the ions referred to.

Acknowledgements.-The author wishes to thank Mr. F. H. Saniter, Director of Research, The United Steel Companies Limited, for permission to publish these data. He would also like to record his gratitude to the late Dr. A. H. Jay under whose direction the work was commenced, and his thanks to Mr. N. Marshall for assistance with some of the calculations.
